Code Optimization – 1

Acknowledgement of material: With changes suited to ANU needs, the slides are obtained from Carnegie Mellon University: https://www.cs.cmu.edu/~213/

Today

- Principles and goals of compiler optimization
- Examples of optimizations

Goals of compiler optimization

Minimize number of instructions

- Don't do calculations more than once
- Don't do unnecessary calculations at all
- Avoid slow instructions (multiplication, division)

Avoid waiting for memory

- Keep everything in registers whenever possible
- Access memory in cache-friendly patterns
- Load data from memory early, and only once

Avoid branching

- Don't make unnecessary decisions at all
- Make it easier for the CPU to predict branch destinations
- "Unroll" loops to spread cost of branches over more instructions

Limits to compiler optimization

Generally cannot improve algorithmic complexity

Only constant factors, but those can be worth 10x or more...

Must not cause any change in program behavior

- Programmer may not care about "edge case" behavior, but compiler does not know that
- Exception: language may declare some changes acceptable

Often only analyze one function at a time

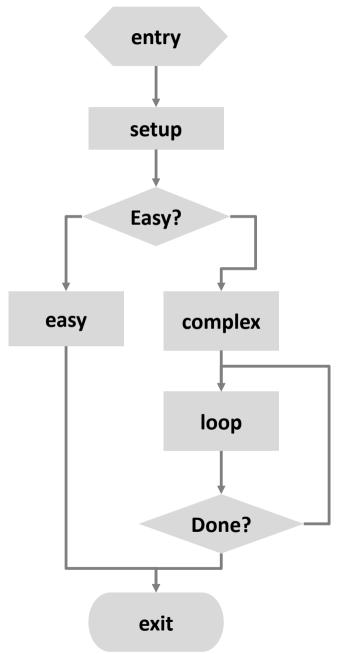

- Whole-program analysis ("LTO") expensive but gaining popularity
- Exception: inlining merges many functions into one

Tricky to anticipate run-time inputs

- Profile-guided optimization can help with common case, but...
- "Worst case" performance can be just as important as "normal"
- Especially for code exposed to malicious input (e.g. network servers)

Two kinds of optimizations

- Local optimizations work inside a single basic block
 - Constant folding, strength reduction, dead code elimination, (local) CSE, ...
- Global optimizations process the entire control flow graph of a function
 - Loop transformations, code motion, (global) CSE, ...

Today

- Principles and goals of compiler optimization
- Examples of optimizations

Try it yourself

- https://godbolt.org/z/Es5s8qsvj
- Go to Godbolt (the compiler explorer) to play around with C and the resulting assembly generated under different compiler optimizations (change the flag from −O3 to −Og, etc. to see more or less aggressive optimization).
- Read descriptions of optimization levels
 - https://gcc.gnu.org/onlinedocs/gcc/Optimize-Options.html

Constant folding

Do arithmetic in the compiler

```
long mask = 0xFF << 8; \rightarrow long mask = 0xFF00;
```

- Any expression with constant inputs can be folded
- Might even be able to remove library calls...

```
size_t namelen = strlen("Harry Bovik"); →
size_t namelen = 11;
```

Dead code elimination

Don't emit code that will never be executed

```
if (0) { puts("Kilroy was here"); }
if (1) { puts("Only bozos on this bus"); }
```

Don't emit code whose result is overwritten

```
x = 23;
 x = 42;
```

- These may look silly, but...
 - Can be produced by other optimizations
 - Assignments to x might be far apart

Common subexpression elimination

Factor out repeated calculations, only do them once

Code motion

- Move calculations out of a loop
- Only valid if every iteration would produce same result

```
long j;
for (j = 0; j < n; j++)
    a[n*i+j] = b[j];

→
long j;
int ni = n*i;
for (j = 0; j < n; j++)
    a[ni+j] = b[j];</pre>
```

Inlining

Copy body of a function into its caller(s)

- Can create opportunities for many other optimizations
- Can make code much bigger and therefore slower (size; i-cache)

```
int pred(int x) {
    if (x == 0)
        return 0;
    else
        return x - 1;
}
int func(int y) {
    return pred(y)
        + pred(0)
        + pred(y+1);
}
```

```
int func(int y) {
  int tmp;
  if (y == 0) tmp = 0; else tmp = y - 1;
  if (0 == 0) tmp += 0; else tmp += 0 - 1;
  if (y+1 == 0) tmp += 0; else tmp += (y + 1) - 1;
  return tmp;
}
```

Inlining

Copy body of a function into its caller(s)

- Can create opportunities for many other optimizations
- Can make code much bigger and therefore slower

```
int pred(int x) {
    if (x == 0)
        return 0;
    else
        return x - 1;
}
int func(int y) {
    return pred(y)
        + pred(0)
        + pred(y+1);
}
```

```
int func(int y) {
  int tmp;
  if (y == 0) tmp = 0; else tmp = y - 1;
  if (0 == 0) tmp += 0; else tmp += 0 - 1;
  if (y+1 == 0) tmp += 0; else tmp += (y + 1) - 1;
  return tmp;
}
```

Does nothing

Can constant fold

Inlining

- Copy body of a function into its caller(s)
 - Can create opportunities for many other optimizations
 - Can make code much bigger and therefore slower

```
int func(int y) {
  int tmp;
  if (y == 0) tmp = 0; else tmp = y - 1;
  if (0 == 0) tmp += 0; else tmp += 0 - 1;
  if (y+1 == 0) tmp += 0; else tmp += (y + 1) - 1;
  return tmp;
}

int func(int y) {
  int tmp = 0;
  if (y != 0) tmp = y - 1;
  if (y != 0) tmp += y;
  return tmp;
}
```

More on Optimization

 We will have another lecture on optimization after understanding memory and caches
